ATOMIC STRUCTURE

ATOMIC STRUCTURE

LEARNING OBJECTIVES:

- Fundamental particles
- Atomic Number & Mass Number
- Isotopes, Isobars & Isoelectronic species
- Radioactivity & Electro Magnetic Radiation
- Atomic models
- Plank's quantum theary Photo electric effect
- Bohr's model
- Spectra and Hydrogen spectrum

Real life applications:

- Φ Atomic structure has several applications in various fields like Nuclear Physics, Chemical Engineering etc....
- Φ Structure of atom helps to know about the Radioactive disintegrations, All the living & processes on the earth

§§ Characteristics of fundamental particles:

PROPERTY	ELECTRON	PROTON	NEUTRON
1. MASS	0.00054 a.m.u.	1.00728 a.m.u.	1.008665 a.m.u.
	9.11X10 ⁻²⁸ g	1.672X10 ⁻²⁴ g	1.675X10 ⁻²⁴ g

MASS	1	1840	1840	4X1840
e/m	1	1/1840	0/1840	2/(4x1840)

Increasing order of specific gravity: n<alpha<p<e-

<u>§§</u>	Important Formulae:
$ $ \Rightarrow	$m_e = \frac{e}{e/m_e} = \frac{1.60x10^{-19}}{1.758820x10^{11}ckg^{-1}}$
	$V = \frac{C}{\lambda}$ or $\lambda = \frac{C}{v}$
$ \Rightarrow$	$E = hv = \frac{hc}{\lambda} = hc \overline{v}$ $hv = hv_0 + \frac{1}{2}m_e V^2$
$ \Rightarrow$	$hv = hv_0 + \frac{1}{2}m_eV^2$
$ \\ \\ \Rightarrow$	Rydberg equation $\overline{\nu} = \frac{1}{\lambda} = R \left[\frac{1}{n_1^2} - \frac{1}{n_2^2} \right]$
$ \Rightarrow$	Maximum number of lines produced when an electron jumps from nth level to ground
 	$level = \frac{n(n-1)}{2}.$
 $ \Rightarrow$	Angular momentum of an electron : $mvr = n \frac{h}{2\pi}$
$ \Rightarrow \Rightarrow \Rightarrow \Rightarrow \Rightarrow \Rightarrow \Rightarrow \Rightarrow \Rightarrow \Rightarrow$	Angular momentum of an electron : $mvr = n \frac{h}{2\pi}$ The radius of Bohr's orbit $r = \frac{n^2h^2}{4\pi^2 m Ze^2}$ The energy of Bohr's orbit $E = \frac{-2\pi^2 m Z^2 e^4}{n^2 h^2}$
	Difference of energy between two Bohr orbits of hydrogen like atoms & ions
⇒ 	$\Delta E = Z^2 Rhc \left[\frac{1}{n_1^2} - \frac{1}{n_2^2} \right]$
$\stackrel{i}{ } \Rightarrow$	Velocity of electron in atom $V = \frac{2\pi Ze^2}{nh} = \frac{2.188 \times 10^8}{n} cm/sec$
$ \Rightarrow$	For H atom, like ions, Ionisation potential $=\frac{-E_1 \times Z^2}{n^2}$
<u>\$\$</u> <u>\$</u> photo Z.	ATOMIC NUMBER AND MASS NUMBER: A neutral atom contains equal number of electrons and protons. The number of electrons or ns present in an atom of an element is called its atomic number. Atomic number is denoted by
	Atomic number is equal to the nuclear positive charge of an element. The sum of protons eutrons in the atom of an element is called its mass number. It is denoted by A. Number of neutrons = A - Z.

Mass number is always a whole number.

Atoms of elements having the same atomic number but different mass numbers are called isotopes. Isotopes of an element have the same number of protons and electrons but differ in the number of neutrons.

|<u>§§</u> <u>ISOTOPES :</u>

Atoms with identical atomic number but different mass numbers are known as isotopes. Isotopes exhibit similar chemical properties.

Eg:-1) Isotopes of hydrogen : Protium $\begin{pmatrix} H^1 \end{pmatrix}$

Deuterium $({}_{1}H^{2})$ or ${}_{1}D^{2}$

Tritium
$$(H^3)$$
 of T^3

2) Isotopes of chlorine are $_{17}Cl^{35}$ and $_{17}Cl^{37}$

It is evident that difference between the isotopes is due to the presence of different number of neutrons present in the nucleus.

For example, considering of hydrogen atom again, 99 985% of hydrogen atoms contain only

one proten. This isotpe is called protium $\binom{1}{1}$ H. Rest of the percentage of hydrogen atom contains

two other isotopes, the one containing 1 proton and 1 neutron is calle deuterium $\binom{2}{1}D,0015\%$ and

the other one possesing 1 proton and 2 neutrons is called tritium $\begin{pmatrix} 3 \\ 1 \end{pmatrix}$. The latter isotope is found in trace amounts on the earth.

§§ ISOBARS :

Atoms with same mass number with different atomic number are known as isobars

 $Eg: {}_{6}C^{14}, {}_{7}N^{14}.$

<u>§§</u> <u>ISOTONES :</u>

The species which are having same number of neutrons are called isotones.

(or)

Atoms of different elements having same number of neutrons but differs in atomic number and mass number.

Eg: ₉F¹⁹, ₁₀Ne²⁰

Eg: ¹⁹₁₉K³⁹, ²⁰₂₀Ca⁴⁰

<u>§§</u> ISOELECTRONIC SPECIES:

The species which are having same number of electrons are called isoelectronic species. Eg: CN^{-} and N_{2}

Eg: Al⁺³ and N⁻³

INTRODUCTION

The term atom was proposed by John Dalton Acording to Dalton's atomic theory, all types of matter is made up of small particles called atoms.Dalton's theory assumed that the atoms were indivisible New experimental facts established that atoms can be further divided into sub atomic particles

1) Electrons 2)Protons 3)Neutrons

Dalton' Theory is able to explain law of consersation of mass, law ofconstant composition and law of multiple proportions. Dalton's law is failed to explain the experiments like when glass or ebonite rubbed with silk or fur generate electricity.

Above experiment indicates that there is a presence of subatomic particles like electron,

neutron proton present in the atom.

Electrons, protons and neutrons are the fundamental particles of atom.Protons and neutrons are present in the nucleusand are called nucleons.Electrons are the negatively charged particles with unit charge and negligible mass. Neutrons are the neutral particles with unit mass.

<u>§§</u> <u>DISCOVERY OF ELECTRON:</u>

Atomic structure was obtained from the experiments on electrical discharge through gases. During the discharge tube experiment "Crookes" observed that rays were found to pass from negatively charged filament (cathode) to positively charged plate (anode) Cathode ray tube is made of glass containing twothin piece of metal, called electrodes, sealed in it. The electical discharge through the gases could be oserved only at very low pressure and at very high voltage. By maintaining low pressure and high voltaindischarge tube current or stream of particlesmoving in the tube from cathode to anode. That rays are known as cathode rays or cathode ray particles.

<u>§§</u> PROPERTIES OF CATHODE RAYS

Cathode rays starts from cathode and move towards anodeThese rays themselves are not visible but their behaviour can be observed with the help ofcertain kind of material (fluorsecent or phosphorescent) wich glow when hit by them Rays travel straight lines in the absence of electric and magnetic field In the presence of electric and magnetic field they are deflected indicates that cathode rays contain negatively charged particles known as electrons Cathode rays found to be independent of nature of the cathode material and nature of the gas in the tube.

<u>¶¶</u> CHARGE TO MASS RATIO OF ELECTRON:

J.J. Thomson measured e/m ratio of the electron based on following points Greater the magnitude of the charge on the particle greater is the deflection when electric and mag netic field is applied Lighter the mass of the particle greater will be the deflection The deflection of electrons from its original path increases when voltage increases from the above points Thomson was able to determine the value of charge to mass ratio as 1.758820 x 10¹¹ ckg⁻¹.

<u>¶</u> CHARGE OF ELECTRON:

Mullikan determined the charged of the electron by an oil drop experiment .By carefully measuring the effect of the electrical field on the movement of many droplets.charge on the oildrops was always an integral multiple of 1.60×10^{-19} C

$$m_e = \frac{e}{e / m_e} = \frac{1.60 \times 10^{-19}}{1.758820 \times 10^{11} c kg^{-1}}$$
$$= 1094 \times 10^{-31} kg$$

The air inside the chamber was ionized by passing a beam of X-rays through it. The electrical charge on these oil droplets was acquired, accelerated or made stationary

depending upon the charge on the droplets and the polarity and strength of the voltage applied to the plate. By carefully measuring the effects of electrical field strength on the motion of oil droplets. Milkan concluded that the magnitude of electrical charge, q, on the droplets is always an integral multiple of the electrical charge, e, that is q = ne, where n = 1,2,3...

M ANODE RAYS(DISCOVERY OF PROTON):

Atom is electrically neutral, there must be some positively charged particles present in the atom to neutralise the negative charges of electrons. Its been confirmed by experiments that atoms contain positively charged particles also. These particles are called **protons**.

GOLDSTEIN experimented with a discharge tube fitted with a perforated cathode and found that a new type of rays came out through the holes in the cathode.

When this experiment is conducted , a faint red glow is observed on the wall behind the cathode. Since these rays originate from the anode, they are called **anode rays**.

cathode. *J.J.Thomson* called these rays positive rays as they are *positively charged*.

<u>SS</u> Properties of anode rays:

1. Anode rays travel along straight paths and hence they cast shadows of objects placed in their path.

2. *They rotate a light paddle wheel placed in their path*. This shows that anode rays are made up of material particles.

3. *They are deflected towards the negative plate of an electric field.* This shows that these rays are positively charged.

4. For different gases used in the discharge tube, the charge to mass ratio (e/m) of the positive particles constituting the positive rays is different. When hydrogen gas is taken in the discharge tube, the e/m value obtained for the positive rays is found to be maximum. Since the value of charge (e) on the positive particle obtained from different gases is the same, the value of m must be minimum for the positive particles obtained from the hydrogen gas. Thus, the positive particle obtained from hydrogen gas is the lightest among all the positive particles obtained from different gases. This particle is called the *proton*.

Origin of positive rays:

In the discharge tube the atoms of gas lose negatively charged electrons. These atoms, thus, acquire a positive charge. The positively charged particle produced from hydrogen gas was called the proton.

H <u>−</u>*e* H⁺ (Proton)

I Characteristics of protons:

1. A Proton is a positively charged particle present in the atoms of all elements.

2. The mass of a proton is **1838** times that of an electron. The relative mass of an proton is equal to **1.005757** *amu* which is taken to be equal to 1 amu. The absolute mass of a proton is **1.672x10**²⁴ g 3. The charge on a proton is equal in magnitude but opposite in sign to that of an electron. The charge carried by a proton is equal to **1.602x10**¹⁹C Which is taken to be one unit of positive charge(i.e., +1). Thus, a proton is said to carry a positive charge.

<u>¶</u> Discovery of neutron:

The helium has 2 electrons and 2 protons . So, the mass of the helium atom was expected to be twice the mass of the hydrogen atom, Which was 1 electron and 1 proton. But, actually the mass of the helium atom is four times that of the hydrogen atom. It was found that atoms of all the elements (except hydrogen) were at least twice as heavy as could be explained by the number of protons they had. To explain that it was predicted that other particles with no charge, but mass equal to that of a proton , must be present in all atoms except hydrogen. This prediction was proved to be correct with the discovery of the neutron.

In 1932, **James Chadwick** bombarded the beryllium with α - particles. He observed the emission of a radiation with the following properties.

1. The radiation was highly penetrating.

2. The radiation remained uneffected in an electric or magnetic field, i.e., the radiation was neutral.

3. The particles constituting the radiation had same mass as that of the proton. Thus the relative mass of such a particle = 1 amu and the absolute mass = 1.6x10-24g. Because of their electrical neutrality, these particles were called **neutrons**.

<u>X - Rays,</u> <u>§§</u>

Roentgen in 1895 showed tha when electrons strike a material in the cathode ray tubes produce rays which can cause fluorescence in the fluorescent materials placed outside the cathode ray tube. Since Roentgen did not know the nature of the radiation he name then x-rays.

X-rays are not deflected by the electric and magnetic fields

X-rays have a very high penetrating power through the matter so these are used to study the interior of the object, X-rays have very short wavelength (0.1nm)

<u>§§</u> Phenomenon of radio activity (α -rays, β -rays γ -rays)

Henri Becqueral observed that there are certian elements which emit radiation (α, β, γ) on their own and named this phenomenon as the radioactivity and the elements known as radioactive elements. α - rays consists of high energy particles carrying two units positive charge and four units of atomic mass (Helium nucle). β -ray are negatively charged particle similar to electrons. γ -rays are high energy radiations like X-rays. Penetrating power order of these radiation is $\alpha < \beta < \gamma$.

NATURE OF ELECTRO MAGNETIC RADIATION: <u>§§</u>

Cosmic rays, γ – rays, X - rays, UV light, visible light, Infrared light, micro waves, TV waves and radio waves are called electromagnetic radiation because they are made up of electric and magnetic fields propagating in perpendicular directions in one another. Electromagnetic radiations have wave characteristics and no medium is required for their propagation. They can travel through the vacuum.

WAVE LENGTH (λ) : The distance between two neighbouring troughs or crests in waves is <u>§</u>§ The units wave length are m, cm, \mathbf{A}^0 , nm, $m\mu$. $1\mathbf{A}^0 = 10^{-8} \text{ cm} = 10^{-10} \text{ m}$ known as wave length.

$$1A^0 = 10^{-8} \text{ cm} = 10^{-10} \text{ m}$$

 $1nm = 10^{-9} m = 10^{-7} cm$

$$1nm = 1m\mu = 10A^0$$

<u>§§</u> **FREQUENCY**: (v): The number of waves that pass through a given point in one second is called frequency.

The units of frequency are sec⁻¹, cycles per second (*cps*) or Hertz (*Hz*).1cps = 1 Hz

WAVE NUMBER $(\overline{\mathbf{V}})$: The number of wave lengths per centimetre or the reciprocal wve <u>§§</u> lengths is called wave number. The unit of wave number is cm^{-1} .

<u>8</u>§ **AMPLITUDE** (a) : The height of the crest or depth of the through of a wave is called amplitude. Amplitude is a measure of the intensity or brightness of a beam of light.

VELOCITY (C): The distance travelled by a wave in one second is called its velocity. **§§** The units of velocity are m/sec or cm/sec.

All types of electromagnetic radiation have the same velocity which is equal to

3x10¹⁰ cm/sec or 3x10⁸ m/sec

4. A is false, R is true.

- **73. A:** Atomic weights of elements are non-intergal
 - R: Elements contain isotopes of different masses.
- **74. A:** The atoms of different elements having same mass number but different atomic number are known as isobars.

R:The sum of protons and neutrons in the isobars is always different.

A: The mass of the nucleus can be either less than or more than the sum of masses of nucleons present in it

 $\ensuremath{\textbf{R}}\xspace$ The whole mass of the atom is considered in the nucleus

NEE

76. A: Electrons in the atoms are held due to coulumb forces

R: The atom is stable only becuase the centripetel force due to columb's law is balanced by the centrifugal force

IV. <u>Matching type</u>

This section contains Matrix-Match Type questions. Each question contains statements given in two columns which have to be matched. Statements (A, B, C, D) in **Column–I** have to be matched with statements (p, q, r, s) in **Column–II**. The answers to these questions have to be appropriately bubbled as illustrated in the following example.

If the correct matches are A-p,A-s,B-r,B-r,C-p,C-q and D-s,then the correct bubbled 4*4 matrix should be as follows:

77. Column-l

- a) Electron
- b) Proton
- c) Neutron
- d) Atomic number

78. Column-l

4

- a) Nucleus
- b) Electro magnetic radiation
- c) Wave length
- d) Frequency

- 5) Einstein

V. <u>Comprehension type</u>

This section contains paragraph. Based upon each paragraph multiple choice questions have to be answered. Each question has 4 choices (A) , (B) ,(C) and (D) out of which **ONLY ONE i**s correct. Choose the correct option.

The frequency (v), wavelength (λ) and velocity of light (c) are related by the equations

 $c = v \lambda$. The other commonly used quantity specially in spectroscopy is the wavenumber($\frac{1}{v}$).

79. Which of the following relations are correct?

1) Frequency × wavelength = Velocity of light

2)
$$\frac{-}{\nu}$$
 = $\frac{1}{\lambda}$ 3) $\lambda = \frac{c}{\nu}$ 4) All of these

§§ ATOMIC MODELS: 11. THOMSON ATOMIC MODEL:

The first atomic model was proposed by *J.J. Thomson,* in 1898. An atom is electrically neutral. It contains positive charges as well as negative charges. According to Thosmon atom is like water melon and elctron's are embedded like seeds in water melon. The positive charge is distributes like fibrous material of water melon. An important feature of this model is that the mass of the atom is assumed to be uniformly distributed over then atom.

It can not explain the results of rutherford's gold foil scattering experiment.

2. RUTHERFORDS MODEL OF ATOM:

Rutherford proposed atomic model is based on α – ray scattering experimentScattering of a narrow beam of α – particles as they passed through a thin gold foil and it is covered with fluorescent ZnS screen. When α – particles struck the screen then flash of light was produced at that point.

OBSERVATIONS :

Most of the α – particles passes through the foil underflected

A small fraction of α – particles were deflected by small angles

A very few α – particles bounced back were deflected by 180°.

CONCLUSIONS:

Most of the space in the atom is empty. A few positive charges were deflected the deflection must be due to enornmous repulsive forces showing that the positive charge of the atom is non speard out the atom.

Main postulates in Rutherford's model

All the positive charge and mass of the atom is present in a very small region at the centre of the atom. It is called nucleus. The size of the nucleus is very small in comparison of the size of the atom. Most of the space outside the nucleus is empty. The electrons revolve round the nucleus like planets revolve round the sun. The centrifugal force arising due to fast moving electrons balances the coulombic force of attraction of the nucleus and the electrons.

Rutherford's atomic model is comparable with the solar system. So it is called planetary model.

DEFFECTS :

1. Stability of atom is not explained.

2. It fails to explain the atomic spectrum or line spectrum.

3. PLANCK'S QUANTUM THEORY :

Substances absorbor emit light discontinuously in the form of small packets or bundles. The smallest packet or energy is called quantum. The radiation is propagated in the form of waves. The energy of a quantum is directly proportional to the frequency of the radiation. $\mathbf{E} \propto \mathbf{v}$

The energy of a quantum is

$$E = hv = \frac{hc}{\lambda} = hc v$$

Where E = Energy in ergs

h = Planck's constant= 6.625×10^{27} erg.sec(or) 6.625×10^{-34} Joule.sec

C = Velocity of light $= 3x10^{10}$ cm/sec $\cdot = 3x10^{8}$ m/sec

v = Frequency of radiation in sec^{-1}

 λ = Wavelength in cm

 \overline{v} = Wave number in $_{Cm^{-1}}$

A body can absorb or emit in wholenumber of quantum

<u>§§</u> PHOTO ELECTRIC EFFECT :

Substances absorb or emit light discontinuously in the form of small particles of energy. The smallest particle of energy is called photon. The energy of a photon in directlyproportional to frequency of the adiation.

The energy of a photon is

$$E = hv = \frac{hc}{\lambda} = hc \overline{v}$$
$$E = \frac{12375}{\lambda} ; \text{ Where } E = \text{Energy in eV} , \ \lambda = \text{wavelength in } A^0$$

The radiation is propagated in the form of photons.

Planck's equations determines both wave nature and particle nature of light. The increase in wave length or decrease in energy of the X - rays after scattering from an object is called the compton effect.

When light is exposed to clean metallic surface, electrons are ejected from the surface. This effect is called photo electric effect. Ejection of electrons from the surface of a metal by irradiating it with light of suitable frequency.

The photo electric effect is readily exhibited by alkali metals like K and Cs.

A part of the energy of photon is used to escape the electron from the attractive forces and the remaining energy is used in increasing the kinetic energy of electron.

$$hv = w + KE$$

 $K.E = \frac{1}{2}m_e v^2, \qquad w = hv_0$

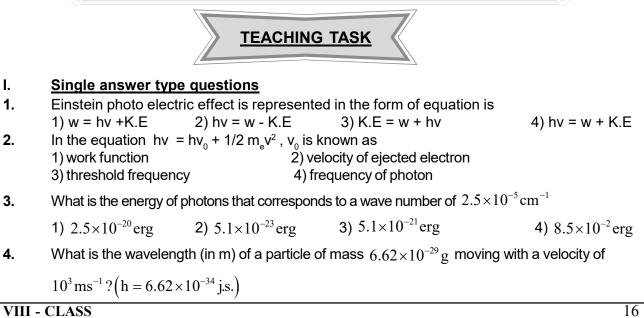

$$\therefore hv = hv_0 + \frac{1}{2}m_eV^2$$

W. DE

Foundation m_e = mass of the electron, V = velocity of the ejected electron

 v_0 = Threshold frequency

"In photo electric effect the number of photo electrons emitted is proportional to intensity of incident light. Kinetic energy of photo electrons depends only on the frequency of incidnet light and not on the intensity of light. The minimum energy required for emission of photo | electrons is called threshold energy or work function."

CHEMISTRY ATOMIC STRUCTURE 2. Both A & R are true and R is not the correct explanation of A 3. A is true, R is false. 4. A is false, R is true. 23. A: The energy of quantum of radiation is given by E=hV. R: Quantum in the energy equation signifies the principal quantum number 24. A: The kinetic energy of the photo electron ejected increases with increase in intensity of incident light R: Increase in intensity of incident of light increases the rate of emission A: Threshold frequency is a characteristic for a metal 25. **R**: Threshold frequency is a maximum frequency required for the ejection of electron from the metal surface 26. A: The kinetic energy of the photo electron ejected increases with increase in intensity of incident light. R: Increase in intensity of incident light increases the rate of emission. Matching type This section contains Matrix-Match Type questions. Each question contains statements given in two columns which have to be matched. Statements (A, B, C, D) in **Column-I** have to be matched with statements (p, q, r, s) in **Column–II**. The answers to these questions have to be appropriately bubbled as illustrated in the following example. If the correct matches are A-p,A-s,B-r,B-r,C-p,C-q and D-s,then the correct bubbled 4*4 matrix should be as follows: List - I 27. List -ll A) Velocity of light 1) Energy particle B) Plank's constant 2) Energy packet C) Wave number 3) 3 x 10⁸ m/sec 4) 6.625 x 10⁻³⁴ J -sec D) Photon 5) cm⁻¹ 28. List - I List -II A) a-ray scattering experiment 1) mosely 2) Planck B) Quantum theory C) Theory of photo electric effect 3) deBroglie D) a-particle equal to 4) He⁺² 5) Rutherford Comprehension type This section contains paragraph. Based upon each paragraph multiple choice questions have to be answered. Each question has 4 choices (A), (B), (C) and (D) out of which ONLY ONE is correct. Choose the correct option. According to Plank's quantum theory, a body can emit or absorb energy not continuously but discontinuously in the form of small packets called quanta. In case of light a quantum is known as a photon. Energy of photon, $E = h_v = \frac{hc}{\lambda} = hcv$ Photoelectric effect: Ejection of electrons from the surface of a metal by irradiating it with light of suitable frequency. VIII - CLASS 19

<u>§§</u> **BOHR'S MODEL**

\mathbb{PP} Postulates of Bohr's atomic model:

The electrons in an atom revolve round the nucleus in definite circular orbits or shells or energy levels.

So far an electron revolves in a certain orbit, its energy remains constant and does not radiate energy. These orbits are called stationary orbits or stationary states.

Electrons can revolve only in those stationary orbits in which their angular momentum is

equal to integral multiple of $\frac{h}{2\pi}$.

 $mvr = n \frac{h}{2\pi}$

where m = mass of electron

v = velocity of electron

r = radius of orbit

h = Plank's constant

When an electron drops from a higher orbit to a lower orbit, energy is released when an electron jumps from a lower orbit to a higher orbit, energy is absorbed. The absorbed or evolved energy is equal to the difference in energies of two orbits, which is equal to Quanta.

$$\Delta E = E_2 - E_1 = hv$$

where E_2 = Energy of higher orbit

 E_1 = Energy of lower orbit

h = Plank's constant

v = Frequency of radiation

Merits of Bohr's model: \mathbb{PP}

- Founda 2021-22 It is successfully explains the hydrogen spectrum and spectra of ions having one electron. i.
- ii. The experimental values of the energies and radii of possible orbits in hydrogen atom are in good agreement with that calculated on the basis of Bohr's theory.
- iii. The experiment value of Rydberg constant for hydrogen is in good agreement with that calculated from Bohr's theory.
- iv. The calculated value of ionisation energy of hydrogen using Bohr's theory is very close to the experimental value.

\mathbb{PP} Limitations of Bohr's model:

i. It failed to explain the spectra of multi electron atoms.

- ii. The fine structure of spectral lines cannot be explained by Bohr's theory.
- iii. It failed to explain Zeeman effect and Stark effect.
- iv. It is against to Heisenberg's uncertainty principle.
- The splitting of spectral lines of an atom into a group of fine lines under the influence of a v. magnetic field is called Zeeman effect.
- The splitting of spectral lines of an atom into group of fine lines under the influence of an vi. electric field is called Stark effect.
- It could not explain the ability of atoms to form molecules by chemical bonds. vii.

1.	Electromagnetic radi	ation of waveler	nght 300nm is just suff	ficient to ionise a sodium atom.
	-			ne ionisation potential of Na.
	1.6.626x10 ⁻¹⁹ j	2.398.7kj	3.6.626x10 ⁻²⁰ j	4.400kj
2.	The wavelength asso of the order.	ociated with a gol	f ball weighing 200 g ar	nd moving at a speed of 5 mh ⁻¹ is (IIT- 2010)
	1) 10 ⁻¹⁰ m	2) 10 ⁻²⁰ m	3) 10 ⁻³⁰ m	4) 10 ⁻⁴⁰ m
3.	Calculate the kinetic	energy of the ele	ctron emitted by an ato	m by 400 nm light when its
			•	ad c = $3 \times 10^8 \mathrm{ms}^{-1}$).(IIT- 2009)
	•			0^{-19} J 4) 3.656 × 10^{-19} J
4.	,	,	etre) associated with a p	,
-† .	at 1x10 ³ m/sec (M _p =	•		(AIEEE -2009)
	1) 0.032nm	2) 40 nm	3) 2.5nmn	4) 14.0nm
	-		,	
	- CLASS			

ATOMIC STRUCTURE

5.	The threshold	frequency v_0	for a metal is	$7.0 \times 10^{14} \mathrm{s}^{-1}$. Calc	culate the kinetic energy of an
	electron emitte	d when radia	tion of frequency	$v = 1.0 \times 10^{15} s^{-1}$	hits the metal.
6.	What will be th	ne wavelength	n of a ball of ma	ss 0.1 kg moving v	with a velocity of 10 ms ⁻¹ .
7.	The debroglie approximately	wave length o	of atennis ball of	mass 60g moving	with avelocity of 10m/s_sec is (AIEEE-2011)
 		kinetic energy ition of wavele	ength 600 n.m . t		4) 10 ⁻³¹ m n the surface of the metal, when nt of energy required to remove
i	1). 2.315x10 ⁻¹	¹⁹ j 2) 3x	:10 ⁻¹⁹ ј	3) 6.02x10 ⁻¹⁹ j	4) 6.62x10 ⁻³⁴ j
9. 	•	•			ic weights are 10.01 and 11.01.
10.	Rutherford's ex	xperiment, wh	nich established	the nuclear model	l of the atom, used a beam of $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
į	(A) β-particles	, which imping	ged on a metal f	oil and got absorb	ed
	(B) γ -rays, wh	ich impinged	on a metal foil a	nd ejected electro	ins
İ	(C) helium ator	ms, which imp	pinged on a met	al foil and got scat	tered
	(D) helium nuc	lei, which imp	inged on a meta	al foil and got scatt	tered
